

Roman Numerals in Idrís

Chris Riess (cr@miavent.com)

Munich Lambda Meetup

XX - Nov - MMXVII

Roman Numerals

- ◆ The ancient Romans used the letters
I, V, X, L,
C, D, and M
to write numbers, such as 1, 2 or 4999

Roman Numerals

- ◆ Each letter represented a value, ie.

I=1, V=5, X=10, L=50

C=100, D=500, M=1000

irrespective of their position in a number

Roman Numerals

- ◆ Those values were simply added to obtain the value of the number, eg.

$$\text{MLXVI} = 1000 + 50 + 10 + 5 + 1 = 1066 \text{ or}$$

$$\text{XXXII} = 10 + 10 + 10 + 1 + 1 = 42$$

Roman Numerals

- ◆ Ordering the letters by their values allowed for the use of subtractive notation, eg.

IIII = 4 became IV

LXXX = 90 became XC

Motivation for this Talk

- ◆ Roman numerals allow us to demonstrate a couple of interesting techniques when implementing conversion functions in Idris, such as using ...

Idris

Category Theory

Rom

- ◆ It would be nice if we could establish a bijection between N and R , ie.
 $g \circ f = \text{id}_N$ and $f \circ g = \text{id}_R$
because, well ...

Homotopy Type Theory

Homotopy Type Theory

- ◆ Just kidding ...

Set Theory

- ◆ ... but we can have ourselves be inspired

Set Theory

- ◆ Bijections allow us to establish equivalences and transport proofs along "discrete paths"
- ◆ Example: $\{\text{true}, \text{false}\} \leftrightarrow \{\text{false}, \text{true}\}$

Set Theory

- ◆ So we want to establish - and prove! - a bijection between (a subset of) the integers and the Roman numerals

Set Theory

- ◆ What about $0, -2, 299'792'458$?
- ◆ What about III and IV ?
- ◆ How do we prove a bijection anyway?

Set Theory

- ◆ A function f is bijective iff it is both injective and surjective, ie.

$$\forall a, b. f(a) = f(b) \Rightarrow a = b$$

$$\forall y. \exists x. f(x) = y$$

Set Theory

- ♦ Ok, we will need some rules ...

Set Theory

- ◆ We will only consider the integers $\{1, \dots, 4999\}$
- ◆ We will not allow subtractive notation (ie. IV)
- ◆ I, X, C, and M may only appear 4 times
V, L, and D may only appear once
- ◆ The letters have to appear in order

Logic and Proof Theory

- ◆ How do we encode those rules?

Logic and Proof Theory

- ◆ We use a Logical Relation!

Logic and Proof Theory

- ♦ ... or kind of - we are still in inspiration mode

Logic and Proof Theory

- ◆ We conjecture that we will get unique Roman numerals with values $\{1, \dots, 4999\}$ (and hence a nice bijection) if we ...

Logic and Proof Theory

- ◆ Allow all letters I, V, X, L, C, D, and M to create single-letter numerals
- ◆ Allow those letters to be prepended to a valid numeral iff the value of the resulting numeral is less than the value of the next higher letter
- ◆ For M, we set this value to 5000

Intuístic Type Theory

- ◆ data Dígit = $I | V | X | L | C | D | M$

Intuistic Type Theory

- ◆ $\text{value} : \text{Digit} \rightarrow \text{Int}$

- ◆ $\text{value } 1 = 1$

$\text{value } 5 = 5$

$\text{value } X = 10$

...

$\text{value } M = 1000$

Intuistic Type Theory

- ◆ $\text{limit} : \text{Digit} \rightarrow \text{Int}$

- ◆ $\text{limit } I = \text{value } V$

$\text{limit } V = \text{value } X$

$\text{limit } X = \text{value } L$

...

$\text{limit } M = 5000$

Intuistic Type Theory

- ◆ data Numeral : List Digit \rightarrow Int \rightarrow Type where
- ◆ SimpleNumeral :
(d: Digit) \rightarrow Numeral [d] (value d)
- ◆ ComplexNumeral :
(d: Digit) \rightarrow (n: Numeral ds v) \rightarrow
True = (limit d) > (value d + v) \rightarrow
Numeral (d::ds) (value d + v)

Intuistic Type Theory

- ◆ ... but let's start coding!

Roman Numerals in Idris

Thank you!
